

## **Pre-Excitation CRDS for Mercury**

Chris Nichols, Kevin Lehmann

*Department of Chemistry, University of Virginia*

Absorbance at 254 nm is traditionally used for detection of mercury. However, mercury shows significant cross sectional absorption area for the excited state transition at 405 nm, an optical region where higher reflectivity mirrors are available. We have produced a novel design using 254 nm light as a pre-excitation source for 405 nm mercury CRDS.
